A Wideband Differentially Fed Circularly Polarized Slotted Patch Antenna with a Large Beamwidth

Wen Li1 · Wei Xue1 · Yingsong Li2,* · Kwok L. Chung3 · Zhixiang Huang2

Abstract

A wideband differentially fed circularly polarized (CP) antenna featuring a slotted patch design with a large beamwidth is presented. The final design of the differentially fed CP antenna, aimed at achieving high gain and a wide axial ratio (AR) bandwidth, involves coupling a differential bending dipole antenna to the slotted patch in the same plane. The presented differentially fed CP antenna demonstrates characteristics of a large AR beamwidth, as verified by simulation and experiment. The measured AR beamwidths of 132.3° in the $xoz$ plane ($\phi = 0°$) and 116.2° in the $yoz$ plane ($\phi = 90°$) are realized at 5.5 GHz. The measured result exhibits broadband performance with a $-10$-dB impedance bandwidth of 78.8% (3.81–8.76 GHz), a 3-dB AR bandwidth of 36.7% (4.78–6.93 GHz), and a maximum gain of 10.2 dBi.

Key Words: Axial Ratio Beamwidth, Circularly Polarized (CP), Differentially Fed, Wideband Antenna.
realize CP radiation and a wide 3-dB ARBW are modifications to rectangular patches, including the addition of four unequal circular patches [11], four bending stubs [12], or rectangular patches with four angled narrow slots [13]. In [14], a 3-dB ARBW of 190° was realized by four three-dimensional radiating patch elements connected by a four-port feeding network with a 90° phase difference. These wide ARBW CP antennas can be utilized for a variety of applications, such as global positioning systems; however, traditional wide ARBW CP patch antennas still often suffer from a narrow 3-dB ARBW.

Multi-feed is another conventional method for widening AR bandwidths. Two feeds with a 90° phase shift [15], three feeds with a 120° phase shift [16], and four feeds with a 90° phase shift [17] have been used to excite the same radiation patch to realize wideband CP radiation. In [18, 19], a wideband four-fed CP antenna array composed of four sequential rotated radiation patches and a four-way feeding network with a phase difference of 90° was designed. Multi-feed CP antennas can yield a broad CP bandwidth and high gain, but they have drawbacks such as a large structure size and complex feeding networks.

To further widen the AR bandwidth, metasurface antennas have been introduced and designed [20–26]. In general, CP metasurface antennas can be excited by two methods: aperture-coupled feed [20–23] and patch-coupled feed [24–26]. In [20], a novel metasurface design utilized unit cells with two pin-loads in the diagonal direction to realize wide CP radiation. The feed system of the CP metasurface antenna in [23] was composed of a cross-slot and a bending microstrip feeding line. In [26], a metasurface-based CP antenna was coupled by a square patch with a tilted slot. Notably, the backward radiation of metasurface-based antennas with aperture-coupled feed is stronger, while the AR bandwidth of patch-coupled metasurface-based antennas is narrow.

Recently, some differentially fed antennas have been proposed in [27, 28]. These antennas, in contrast to conventional single-ended antennas, do not necessitate the use of redundant baluns or 180° hybrids. As a result, they are widely utilized in differential microwave circuits. In [29], the presented differentially fed CP antenna, which was designed to achieve a wide AR bandwidth, consisted of two cross-dipoles and phase shifters. In [30], a series-fed CP differential antenna, which utilized wideband phase shifters and crossed open slot pairs, realized a wide 3-dB ARBW.

In this paper, a wideband differentially fed CP slotted patch antenna is presented, and the linearly polarized differentially fed dipole antenna is bent for achieving CP radiation. Two centro-symmetric coupling patches and slotted patches are added in the simulation to the surface of the bending dipole antennas to further extend the AR bandwidth and impedance bandwidth. When the slotted patch is used, the final differentially fed CP antenna achieves high gain and wideband CP radiation. The measured result exhibits broadband performance with a −10-dB impedance bandwidth of 78.8% (3.81–8.76 GHz), a 3-dB ARBW of 36.7% (4.78–6.93 GHz), and a maximum gain of 10.2 dBiC.

II. ANTENNA DESIGN AND PERFORMANCE

1. Antenna Geometry

Fig. 1 shows the structure of the presented differentially fed CP antenna from various angles, including three-dimensional, side, top, and bottom views. The material of Layer 1 with a thickness (h1) of 3 mm is designated as F4BM, whose relative dielectric constant is 2.2 and the loss tangent is 0.0025. Material Rogers 4003C is utilized for Layer 2 with a thickness (h3) of 0.8 mm to reduce the antenna cost, whose relative permittivity is 3.55 and the loss tangent is 0.002. Fig. 1(b) shows the air gap (h2) between Layer 1 and Layer 2 with a thickness of 2 mm. The driven bending dipole and slotted patch are fabricated on top of Layer 1. The differential microstrip feeding line is fabricated at the bottom of Layer 2. The presented differentially fed CP antenna was optimized using Computer Simulation Technology (CST) Microwave software to determine the final

![Fig. 1. Structure of the presented CP antenna: (a) three-dimensional view, (b) side view, (c) top view, and (c) bottom view.](image-url)
parameters, resulting in the following values (in mm): \( L_1 = 0.3 \), \( L_2 = 3 \), \( H_m = 1.3 \), \( H_t = 3 \), \( H_2 = 3 \), \( S_1 = 11.3 \), \( S_2 = 5 \), \( W_0 = 1.8 \), \( F_1 = 3 \), \( F_2 = 1.5 \), \( F_3 = 1.5 \), \( R_1 = 9.35 \), \( R_2 = 18 \), \( H_t = 0.5 \), \( W_p = 9 \), and \( G = 80 \).

2. Operating Principles and Analysis of Wideband CP Antennas

Three prototypes of differentially fed CP antennas are presented in Fig. 2 to illustrate the design process. The dimensions of the three antenna prototypes are the same as those of the original antenna.

The conventional dipole antenna is bent to form Ant-1. To better investigate the principle of the bending dipole forming circular polarization and to determine the size of the bending dipole, the mode current and resonant frequency of the dipole in free space as well as the mode current, resonant frequency, and AR of the bending dipole in free space are given in Fig. 3. As shown in Fig. 4(a), the length of the dipole allows the first resonant frequency of the dipole, \( M_{d1} \), to be calculated around 2 GHz, and the corresponding mode current is \( J_{d10} \). By observing the distribution of the mode currents \( J_{d21} \) and \( J_{d22} \) in the second mode, it can be found that the second resonant frequency is around 6 GHz.

![Fig. 2. Evolution of the proposed antenna.](image)

![Fig. 3. Simulated results of different evolution antennas: (a) reflection coefficient and (b) axial ratio.](image)

![Fig. 4. (a) Mode current and resonant frequency of the dipoles in free space. (b) Mode current, resonant frequency, and axial ratio of the bending dipole in free space.](image)

The difference between the two mode currents of the conventional dipole is that the mode current \( J_{d10} \) of \( M_{d1} \) is oriented in the same direction, while the mode currents \( J_{d21} \) and \( J_{d22} \) of \( M_{d2} \) are reversed. Fig. 4(b) shows the mode currents, resonant frequencies, and AR of the bending dipole in the free space, where the total length of the bending dipole is the same as that of the conventional dipole above. It can be seen that the current distributions of the newly formed mode currents \( J_{b21} \), \( J_{b22} \), and \( J_{b10} \) are the same as before bending, and the changes in resonant frequencies of their corresponding \( M_{b1} \) and \( M_{b2} \) are also minimal. Since the first resonant mode \( M_{d1} \) of the conventional dipole corresponds to the current \( J_{d10} \), which is oriented in the
same direction, the corresponding current $J_{b10}$ of the bending dipole can generate orthogonal mode currents, but the 90° phase difference required for the formation of CP radiation cannot be generated. The second resonant mode $M_{d2}$ of the conventional dipole corresponds to the currents $J_{d21}$ and $J_{d22}$, which are reversed, so the corresponding currents $J_{b21}$ and $J_{b22}$ of the bending dipole can produce a 90° phase difference by introducing a difference in the lengths of the horizontal and vertical radiating structures at one end of the bending dipole, approximately 0.25λ.

The AR of the final bending dipole in Fig. 4(b) changes considerably around 6 GHz. As mentioned above, dielectric and grounding plates are added to Ant-1 to obtain radiation in the broadside direction, as opposed to the bending dipole in free space. As shown in Fig. 2, the resonant frequency of Ant-1 is around 6 GHz and shows a tendency toward CP radiation, evident from the AR measurements around 6 GHz.

Ant-2 is formed by adding two asymmetric coupling patches to Ant-1 to extend the AR bandwidth. Fig. 2 shows that after adding the two centrosymmetric coupling patches, the resonant frequency of Ant-2 shifts to 5 GHz and AR is below 10 at 6 GHz. However, the AR of Ant-2 is no less than 3 dB in the desired bandwidth.

The final step is to achieve broadband CP radiation using a 4 × 4 unit cell radiation structure coupled by the bending dipole. This configuration was tested in three different states: state A, where the unit cell structure was placed on top of the bending dipole; state B, where the unit cell structure and the bending dipole were placed in the same plane (representing the final antenna design); and state C, where the unit cell radiating structure was placed underneath the bending dipole. A three-dimensional structure of states A and C, along with the reflection coefficients and AR for these three cases, is provided in Fig. 5. It is evident from Fig. 5(c) and 5(d) that the reflection coefficients and AR corresponding to states A and C do not achieve the desired broadband effect. Ultimately, the simulated −10-dB impedance bandwidth of 56.9% (4.1–7.36 GHz) and 3-dB ARBW of 32.3% (4.93–6.83 GHz) were achieved by placing the bending dipole in the same plane as the unit cell radiation structure (Ant-3).

### 3. Antenna Design Guidelines

The wideband differentially fed CP antenna was created through the following steps:

**Step 1:** Create a bending dipole with a total length of about 1.5λ0 at 6 GHz, which corresponds to 0.5λ0 at 2 GHz. Ensure that the difference in length between the horizontally radiating and vertically radiating structures at one end of the bending dipole ($R_1$-$R_0$) is about 0.25λ0.

**Step 2:** Add a ground plane to adjust the height of the ground plane and the bending dipole. Add asymmetric coupling patches and investigate whether the antenna can achieve broadband CP radiation by optimizing the dimensions of the structure.

**Step 3:** Add a 4 × 4 unit cell patch, placing it in the same plane as the bending dipole. Add a stub at one end of the vertical radiation structure of the bending dipole and adjust the length ($L_2$). A wideband differentially fed CP antenna is then created.

### 4. Parametric Study

Parametric studies were conducted to determine the final dimensions. The performance of the presented differentially fed CP antenna is influenced by numerous parameters. In this study, the key parameter $L_2$ was selected. Fig. 6 illustrates how the length $L_2$ affects AR, with the reflection coefficient and ARBW being notably sensitive to changes in $L_2$. This is because the length of $L_2$ affects the current strength along the y-direction. Ultimately, a value of $L_2 = 3$ mm was selected as the final size for the proposed differentially fed CP antenna.

### III. EXPERIMENT VERIFICATION

The prototype, as depicted in Fig. 7, was fabricated to validate the simulation results of the presented CP antenna. The Agilent N5062A network analyzer was utilized to measure the S-parameters. The anechoic chamber was used to test radiation.
characteristics, including gains and ARs. A power divider with a 180° phase difference was used in the tests. Fig. 8(a) shows that the simulated -10-dB impedance bandwidth is 56.9% (4.10–7.36 GHz) and the measured -10-dB impedance bandwidth is 78.8% (3.81–8.76 GHz). The difference between the measured and simulated reflection coefficient can be attributed to the idealized differential feed used in the simulation, where the amplitude and phase differences of each port are assumed to be equal across all frequency ranges, while, in reality, the power divider exhibits variations. Fig. 8(b) shows a simulated 3-dB ARBW of 32.3% (4.93–6.83 GHz) compared to a measured ARBW of 36.7% (4.78–6.93 GHz).

The differentially fed antenna demonstrates the characteristics of a large ARBW, as verified by simulation and experiment. As shown in Fig. 9(a), the ARBWs of 132.3° in the \(xoz\) plane and 116.2° in the \(yoz\) plane are realized at 5.5 GHz. The simulated and measured normalized radiation patterns at 5.5 GHz are shown in Fig. 9(b). Fig. 10 demonstrates the normal...
malized radiation patterns at significant frequencies of 5.2, 6, and 6.8 GHz. The normalized right-hand CP is clearly greater than the normalized left-hand CP in the z-axis direction. The measured radiation patterns closely resemble those obtained from simulation, indicating a high degree of similarity.

IV. PERFORMANCE COMPARISON

Table 1 provides a comparison of various parameters, including thickness, bandwidth, and peak gain, for different antennas. The crossed-dipole antennas in [8–10] showed a wide −10-dB impedance bandwidth and 3-dB ARBW, but they had a high profile. The CP antennas in [11–14] exhibited a wide 3-dB ARBW but suffered from a limited 3-dB ARBW. The antennas in [20, 23, 26] were low-profile metasurface-based designs. In [20, 23], incomplete ground planes were used to achieve 3-dB ARBW of 14.9% and 20.9%, respectively. A 3-dB ARBW of 17.5% was achieved with the antenna in [26] fed by a slotted patch. The differentially fed CP antennas in [29, 30] with a high profile showed a wide 3-dB ARBW, but the peak gain was less than 8.5 dBi.

V. CONCLUSION

This paper presents a novel differentially fed antenna design with a wide 3-dB ARBW and a wide ARBW. We compared the resonant frequencies and mode currents of a conventional dipole antenna and a bending dipole antenna to identify the resonant modes responsible for CP radiation and determine the source of the phase difference in the orthogonal mode current. Our findings reveal that placing the bending dipole excitation structure in the same plane as the unit cell radiation structure enables the generation of a broad 3-dB ARBW. Experimental results demonstrate that our proposed differentially fed CP antenna exhibits an impressive ARBW of 132.3° in the xoz plane and 116.2° in the yoz plane at 5.5 GHz.

Furthermore, our results show a measured (10 dB) impedance bandwidth of 78.8% (3.81–8.76 GHz) and a measured (3-dB) ARBW of 36.7% (4.78–6.93 GHz). It is worth noting that the overlapping bandwidth indicates excellent AR performance for this antenna design.
